                                                                                                                                                                                                                                                                                                                                                                                                       <u>ن</u>
                                                                                                                                                                                                                                                                 the fusion proteins, thus allowing folding of the fused institutions at commercially useful high concentrations. The procedural steps of expanagen bromide cleavage, oxidative sulphitritysis and related to purification steps can thus be eliminated, along with the use of high concentrations of mercaptan or the use of hydrophobic absorbent essins.
                                                 This sequence represents a chimeric protein, hGH-mini-prolinguille.
This chimeric protein contains an N-terminal fraqment of human growth hormone (hGH) of the sequence given in ANY42855, a sleavable peptide linker (ANY42857), and a human insulin precursor comprising insulin A and B chains (ANY42859). The hGH portion of the chimeric protein acts as an intramolecular chapterone (LMC) for the insulin precursor, enabling it to fold correctly. The cleavable peptide linker has a C-terminal Arg residue which enables the hGH portion of the chimeric protein to be removed after folding has taken place. Production
                                                                                                                                                                      of recombinant human insulin via an hoH-proinsulin chimeric protein can provide human insulin with correctly linked cysteine bridges with fewer necessary procedural steps, and hence resulting in a higher viola of human insulin. The IMC sequences not only protect insulin sequences from intracellular decradation by a micrororganism host, but also provide the folding of the fused insulin precision: familiar time solubility of the fused insulin precision. Additional additional and decrease the intermedental interactions among the fusion protein and decrease the intermedental interactions among
                                                                                                                                                                                                                                                                                                                                                                                                                               New chimeric proteins containing human growth hordone fragment, used

This sequence represents a chimeric protein, which contains an N-terminal fragment of human growth hormone (hGH) of the sequence given in AAX42856, a cleavable peptide linker (AAX4285), and a human insulin precursor comprising insulin A and B chains (AAX42859). The HGH portion of the chimeric protein acts as an intramplecular chaperone (IMC) for the chimeric protein acts as an intramplecular chaperone (IMC) for the chimeric protein acts as an intramplecular chaperone (IMC) for the chimeric protein at a C-terminal Arg residue which enables the hGH portion of the chimeric protein to be removed after folding has taken place. The chimeric protein to be removed after folding has taken place or protein can provide human insulin with correctly linked cysteine bridges with fewer necessary procedural steps, and hence resulting in a higher protein of human insulin with correctly linked cysteine bridges with fewer necessary procedural steps, and hence resulting in a higher sequences from intracellular degradation by a microorganism host, but also promote the folding of the fused insulin precursor, facilitate the solubility of the fusion protein and decrease the intermolecular.
                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          interactions among the fusion proteins, thus allowing folding of the first insulin precursor at commercially useful high concentrations. The procedural steps of opening bromide cleavage, oxidative sulphitolysis and related purification steps can thus be eliminated, along with the use of high concentrations of mercaptam or the use of hydrophobic absorbent
                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        (1) TESNKEETQQKSNEELLRISILLIOSMLEPVQLGTGPRFVNQELGGSHEVEALYLVGGBR 120
                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           64 ------

with a rereaptan to provide 2-10 SH residues per Cys residue, in presence of a charterpic agent and in ag. medium of pH 10-11.

Treating the proof with 3-50 g hydrophobic adsorber resin per i ag. medium of pH 4-7, isolation, the adsorbed resin and pro-insulin and desorbing the pro-insulin. This method produces pro-insulin with correctly bonded Cys bridges. Compared with Known methods it involves fewer stages (egs. no sulphitolysis or cyanogen bromide cleavage) and overall losses during purification are reduced, i.e. the process is quicker and gives better yields.

Sequences of insulin chain A, B and C are given in AAR68895-97.

Sequences of finsulin -4 are given in AAR68898-901.

The insulin produced can then be purified. This sequence is a SOD-insulin B chain-Lys-Arg-insulin B chain-Lys-Arg-insulin B chain hybrid polypeptide and is encoded by the plasmid construct pBAST-R. Transformation of the proper E.coli
                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      Recombinant insulin prodo, by correctly folding pro-insulin hybrid polypeptide - then enzymatic cleavage of folded product, does not require sulphite protection of SH nor use of cyanogen bromide
                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               A new method for the production of recombinant human insulin

                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      Saps
                                                Recombinant insatin produ. To correctly folding pre insulfic hypolopolypoptide - Then enzymatic eleavage of tolded product, does not require salphite protection of SB not use of eyanosen browide.
                                                                                                                                                  A new method for the production of recontinant human invitin comprises folding a hybrid polypepilde comprising profitsuit inder conditions that permit correct disalphide bond formation and subjecting that folded protein to englighte cleavage. The insulin produced can then be purified. This sequence is a SCD-insulin Behain-ray insulin A chain hybrid polypepilde and is encoded by the plasmid construct poBASC-LAT. Transformation of the properties to the profitsuit hybrid polypepilde and is encoded by the profit of the profit hybrid polypepilde. Wastel for human insulin production. The method produces recombinant human insulin identical to the natural hommone. Hazardous and cumbersome
                                                                                                                                                                                                                                                                                                                                           procedures involving eyanogen bromide and suiphitolysis to protect SH groups are avoided since the entire hybrid polypoptide folds efficiently to the native structure even with the leader attached

ArgB1 comprises the B and A chains of a claimed buran insulin derivative. In the final claimed compen. they are covalently connected via disulphide honds between Cys residues AVAP7 and
host cells with pBAST-R results in the efficient expression of the profusulin hybrid polypeptide, useful for buran insulin production. The method produces recombined human insulin identical to the natural hormone. Hazardous and cumbersome procedures involving expangen bromide and sulfahitolysis to protect SH groups are avoided since the entire hybrid polypeptide folds efficiently to the native structure even with the loader altached and Tys unprotected.

Pro-insulin is produced by treating recombinant precursor protein with a mercaptan to provide 2-10 SH residues per Cys residue, in preeded agent and in aq. medium of pH 10-11, irecting the prod. with 3-50 g hydrophobic adsorber resin per 1 aq. medium of pH 4-7, isolating the adsorbed resin and pro-insulin and desorbing the pro-insulin. This method produces pro-insulin and correctly bonded Cys bridges. Compared with known methods it involves fewer stages (esp. no sulphitolysis or cyanogen bromide the process is quicker and gives better yields.

C Sequences of insulin chain A, B and C are given in AAR68895-97.

Sequences of pro-insulin 1-4 are given in AAR68898-901.

which contains an example of a profession molecule correspond to the general formula R2-R4. (B2-B25)-TX-Giy-(A2-A20)-R3 (11). In formula (11), X = Lys. Arg or appetite of 2-55 amino acids contage to Arg at the N- and C-remini; Y • a natural amino acid; R1 = C Phe or a bond; R2 = H, Arg. Lys. a peptide of 2-45 amino acids contage. Arg or Lys at the N- and C-termini; R3 • a natural amino acid; (A2-A20) and (B2-B29) are the insulin A- and B-chain sequence acid; (A2-A20) and (B2-B29) are the insulin A- and B-chain sequence from human or other Insulin. The profusulin molecule, released by cyanogen bromide, is reacted with mercaptan at a ratio of 2-10 Si residues of mercaptan per Cys residue of profusulin. The reaction: C takes place in the presence of a chaotropic auxiliary agent at PH 10-11 and results. In profusulin with correctly linked cystine or bridges. Reaction with trypsin and opt. Carboxyperidates Bysician correctly folded insulin. The insulin is isolated by absortion on
                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       isolation of insulin that is correctly post-translationally processed - by reacting pro-insulin with a mercaptan in the prosence of a chaotropic agent and purifice, after absorption to hydrophobic
                                                                                                                                                                                                                                                                                                                                                                                                  Proinsulin; post-translational modification; recombinant production; protein folding; conformation.
                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        present sequence is that of a fusion protein, produced in E.coll

                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          AAQ86429 encodes AAR71694 mating factor alpha 1-Insulin precursor ArgB1, ArgB1 N-terminal EEAEAEAR. The insulin precursor comprises the H and A chains of a claimed human insulin derivative preceded by the N-terminal amino acids EEAEAEAR. In the final claimed compsn. they are covalently connected via disulphide honds between Cys residues A7/B7 and A20/B19. The derivative, which may be present as a zinc ion complex, can be used as a fast action treatment for diabetes.
                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             Gaps

                                            ArgBl. ArgB31 N-terminal EDASAEABN. The insulin precursor comprises the B and A chains of a claumed bumen insuling destinative for co-doct by the N-terminal amino acids REARAMER. In the final claimed roungs, they are covalently connected via disulphide behaves the
precursor Andil, Arghill dissers; Zinc les somplex; alpha ); N-terminal EEAEASAFK.
                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             residues AZ/B7 and AZB/H15. The derivative, which may be present as a zinc ton complex, can be used as a fast action treatment tot diabetes.
                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          AAO86432 encodes AAR71695 matting factor alpha 1-finsilin precursor
                                                                                                                                                                         Mating factor alpha 1-Insplin precursor Argsl, Aras31 N-terminal.
                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        Acylated insulin deliv, which may be present as a Zinc Ton complex - is used to treat diabetes and is rapid acting.
                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               Jonassen I;

This sequence represents a human insulin precursor comprising insulin And Bechins. This insulin precursor is a component of the chimeric proteins And Bechins. This insulin (And 2086) and the chimeric protein and given in AND 42861. These chimeric proteins additionally contain an N-terminal fragment of human growth hormone (hGH) and a cleavable peptide linker (AND 4887). The hGH portion of the chimeric protein acts as an intrample cular chaperone (HMC) for the insulin precursor, enabling it to fold correctly. The cleavable peptide linker has a climeric protein to be removed after folding has taken place. Production of the chimeric protein to be removed after folding has taken place. Production of recombinant human insulin via an hGH-proinsulin chimeric protein can provide human insulin with correctly linked cysteine bridges with provide human insulin with correctly linked cysteine bridges with fewer necessary procedural steps, and hence resulting in a higher yield of human insulin. The INC sequences not only protect insulin sequences from intracollular degradation by a microorganism host, but also promote the finsion proteins and decrease the intermolecular interactions among the fusion proteins. This allowing of the insulin precursor. The fusion proteins.
                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             0;
                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 the fusion proteins, this allowing folding of the fused insulin precure at commercially useful high concentrations. The procedural steps of cyanocen bromide cleavage, oxidative subhittolysis and related purification steps can thus be eliminated, along with the use of high concentrations of mercaptan or the use of hydrophobic absorbent resins.
                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             Gaps

                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      This sequence is joined to the C-terminus of an N-terminal transcur. comprising opt. modified 'endamistate. This fusion protein may be converted into human insulin using known methods. The synthetic gene was prepared by the phosphoramidite method. See also AAOQ4336.

This anchoring technique can provide for the release of the product in a highly specific and selective manner. In addition, the recombinant protein will contain an epitope which can be used in its final purinication by immunosifinity. The protein product can be released by e.g. nitrous domination or treatment with neutral detergent.
                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         Gaps
                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        Recombinant produ. of proteins, e.g. insulin - by producing the protein with a glycosyliphosphatidylinositol anchor followed by selective release.
